Introduction. A problem

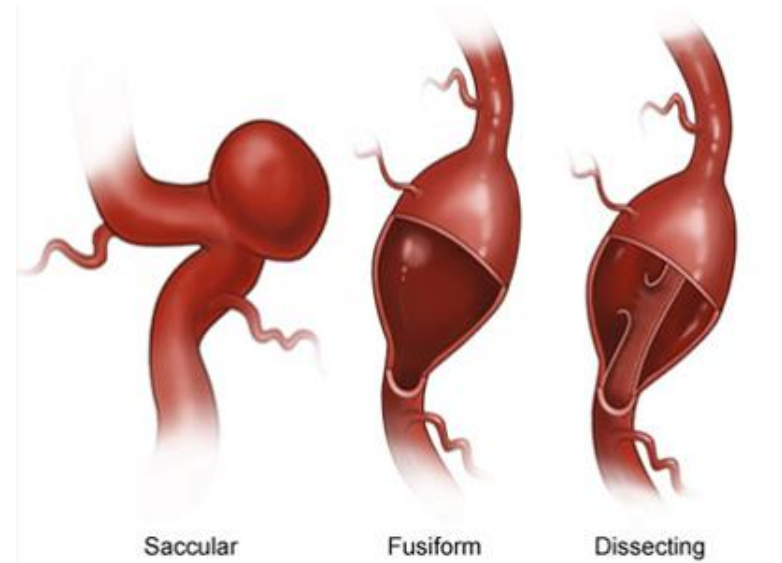

Top 10 global causes of deaths, 2016

Source: Global Health Estimates 2016: Deaths by Cause, Age, Sex, by Country and by Region, 2000-2016. Geneva, World Health Organization; 2018.

© WHO

According to W.H.O. aneurysm associated diseases are among the most common causes of death in the world.

© Mayo Clinic

Types of aneurysm:

- Saccular,
- Fusiform,
- Dissecting;

Introduction. A problem

Is surgery necessary?

Risk of rupture ~ Risk of developing postoperative complications (0.6%)!!!

PART I. Clinical monitoring

The aim

- Develop the measurement device and information complex for endovascular intraoperative monitoring
- Create the database for monitoring of the hydrodynamic parameters of blood flow
- Optimize neurosurgeon operations

Pressure and blood flow rate measurement

Pressure and velocity
measurement sensor:
diameter ≈ 0.36 mm
length ≈ 1.85 m

Monitoring

Monitoring of neurosurgery operations includes:

- Select the data with best quality
- Clean the data - remove noise ([wavelet analysis](#))
- Make the phase diagrams «[velocity-pressure](#)», «[flow rate-flux of energy](#)» (during neurosurgical operation)
- Make operations maps
- Make the phase diagrams «[velocity-pressure](#)», «[flow rate-flux of energy](#)» (before and after operation)

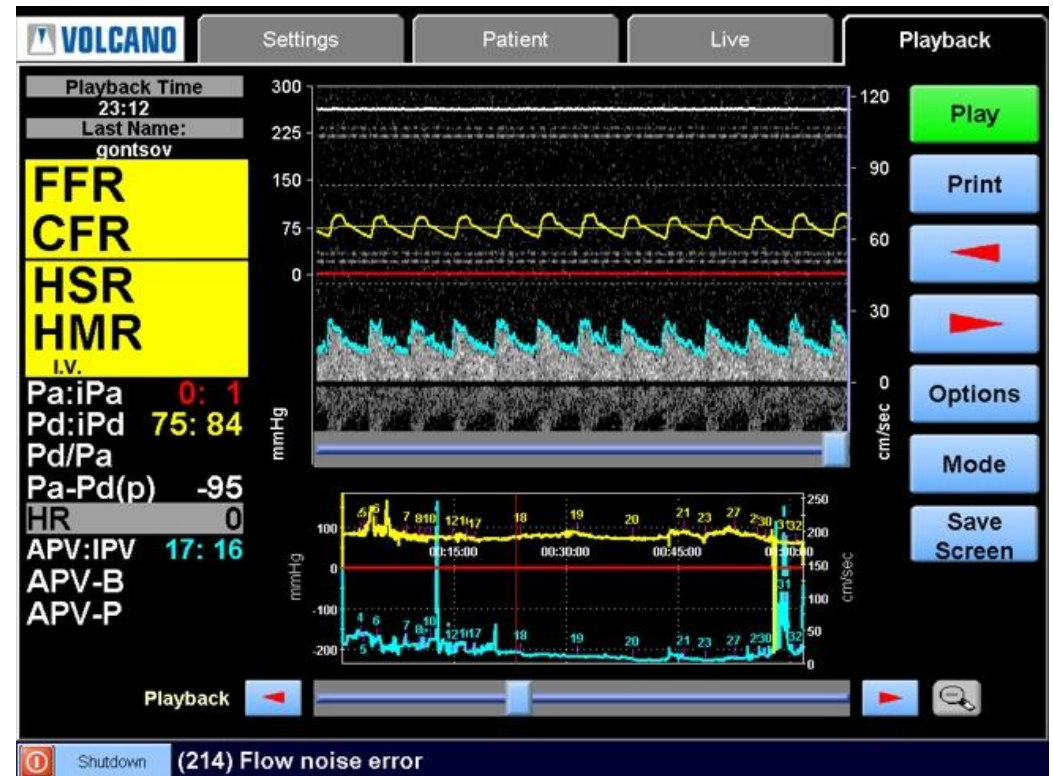

Monitoring was made for ≈ 50 neurosurgical operations of arteriovenous malformations and cerebral aneurysms in Meshalkin NRICP.

Part II. Nonlinear oscillator

The generalized equation of Van der Pol - Duffing

- To identify the character of parameters behavior in the area of pathologies we use the model of generalized equation of the Van der Pol - Duffing

$$\varepsilon q'' + (a_1 + a_2 q + a_3 q^2) q' + b_1 q + b_2 q^2 + b_3 q^3 = ku,$$

$$a_i, b_i, k \in R; \quad i = 1, 2, 3;$$

- Velocity u – is given value, pressure q – the solution to the equation
- The coefficients are based on experimental data:
 b_i responds for the elastic properties of blood vessels, a_i responds for the viscous friction, ε corresponds to the relaxation character of the oscillations

Experimental verification of the model

- The model has been experimentally confirmed in a large number of clinical data obtained during operation in Meshalkin NRICP
- It is shown that the equation well reproduces clinical data

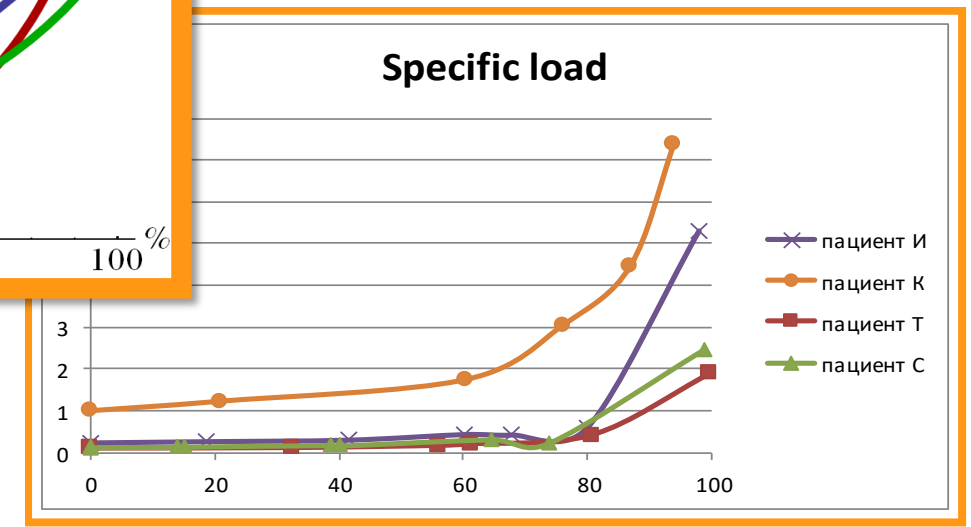

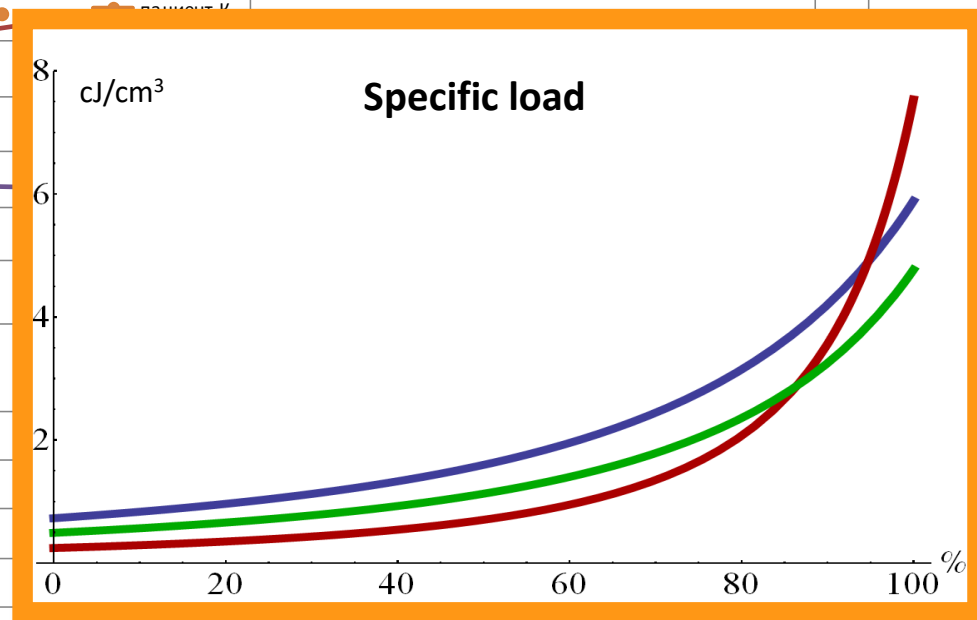

Part III. Assessment of the AVM embolization

Hemodynamic characteristics

- ▷ **Flow rate** $Q = vS$ – the volumetric flow rate through vessel cross section per unit of time
- ▷ **Total pressure** $P = p + \alpha\rho v^2/2$ – the energy (sum of potential and kinetic energy) which transported on one unit of blood volume;
 ρ - the density of blood, α - the Coriolis coefficient
- ▷ **Energy flow rate** $E = QP$ – the total energy which transported by blood through vessel cross section per unit of time
- ▷ **Loads** $W = E_1 - E_2$, E_1 – the amount of energy which obtain AVM through all the afferents, E_2 - the amount of energy which released from AVM through draining vein
- ▷ **Specific load** $w = W/V$, V – the volume of AVM

Dependence on the degree of AVM embolization

(54) **METHOD FOR INTRAOPERATIVE DOPPLER CONTROL OF RADICALITY OF ARTERIOVENOUS MALFORMATION EMBOLISATION**

(57) Abstract:

FIELD: medicine.

SUBSTANCE: invention concerns medicine, particularly neurosurgery. A DMSO-compatible microcatheter for administering the non-adhesive composition Onyx is inserted endovascularly through an arteriovenous malformation (AVM) afferent intranidally. A reinforced microcatheter of an internal diameter not less than 0.43 mm (0.17 in) is inserted into the afferent in the proximal direction from an origin of intact arteries not involved into the AVM blood flow; an intravascular conductor Combomap is inserted through the microcatheter into an arterial lumen. Immediately before an embolisation procedure and throughout the operation, Combomap apparatus is used for intravascular Doppler sonography with bypass pattern fixation; the pressure is measured in the AVM afferent at a distal end of the intravascular conductor Combomap and in a radial artery. The blood flow velocity in the AVM afferent and the pressure values in the radial artery and in the AVM afferent are

indicated by Combomap apparatus with using an analogue-to-digital converter and programmed to derive hemodynamic values in the embolised AVM afferent - P and V, Q and E. The intraoperative real-time dependency diagrams of V and P, Q and E are plotted; the composition Onyx is administered until a linear blood velocity in the AVM afferent is reduced; the bypass pattern regresses completely; the AVM afferent pressure is levelled with the radial artery pressure; the plotted hemodynamic values V and P, Q and E tend to decrease. That is followed by a control angiography, and if the radicality of the AVM exclusion has been proved, an endovascular instrument is removed, and the operation is completed.

EFFECT: method enables minimising the quantity of the angiography stages that substantially reduces the intraoperative radiation exposure accompanying the endovascular operation.

Monitoring results

- Modeling the specific load during embolization;
New concept of endovascular AVM embolization
- Quantitative description of the hysteresis parameters of blood flow in AVM embolization
- Analysis of blood flow parameters for the treatment of AA: the alignment of the resistances on various sections of the circulatory network
- Creating the database of information
- Developed protocol of AVM embolization

Part IV. Rheology and hystology of cerebral aneurysm tissue

Introduction. Causes of rupture

What affects the aneurysm growth and rupture?

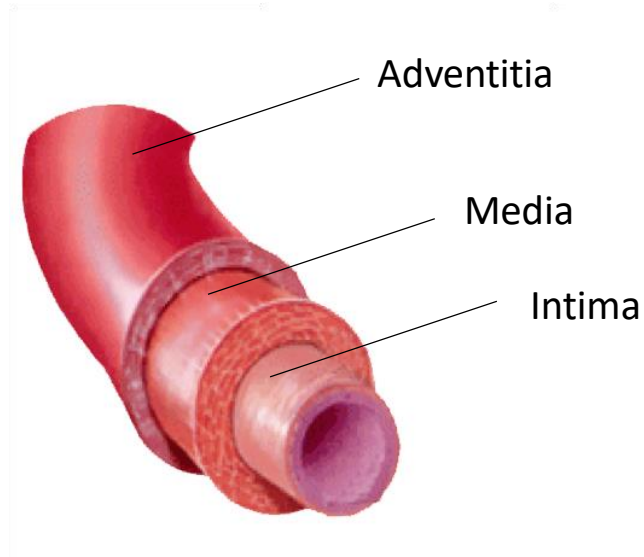

Hemodynamical factors

Vs

Tissue inflammation & degeneration factors

Differences in aneurysm's and healthy vessel structure

Healthy vessel

Aneurysm wall has a complex structure with alternating layers of healthy and damaged tissue.

Specimen shape

Rectangular shape

Dog-bone shape

Methods. Stages of the loading

While conducting the experiment we took into account well-known phenomenon for biological tissues – **preconditioning**. The need to consider this phenomenon was due to the significant role of the matrix in the mechanics of such tissue. Taking into account its relaxation during the experiments ensures that the true stresses in the sample are correctly accounted for. This technique was used for the initial stages (stage 1-5 depending on the sample), and in the next stages the effect of this condition was not noticed.

The distribution of collagen fibers in the vessel tissue

Collagen fibers in the tissues of a healthy vessel is directed at an angle of 30-50 degrees to the axis of the vessel. Due to the random destruction of layers in the dome of the aneurysm and the growth of connective tissue, the aneurysmal tissue does not have a similarly ordered structure.

Conclusions

The result of a mechanical test of 12 aneurysm samples and one artery is given;

Mooney-Rivlin, Yeoh and Neo-Hookean models for each test are built;

The hierarchy of hyperelastic models is created based on the results of the approximation;

The jumps on stress-strain diagrams analyzed.

Part V. Laser induced fluorescence as
a method of classification of cerebral
aneurysm tissue

Fluorescence

The 210-350 nm laser is used with the size of spot approximately 5x14 mm. Fluorescence spectra of resected vessels' fragments were measured. During the spectrometer's exposure time (1 sec.) the emitting pulses were accumulated. The linearity of fluorescence was monitored. Pulse energy did not exceed 200 mJ per pulse. The measurements in laser wavelength diapason 210-290 nm were performed using a special filter (short-wave boundary at 300 nm), in 300-350 nm – using BC-8 filter. Each spectrum was normalized with total energy of laser irradiation during the exposure time and relative spectral sensitivity of the spectrometer.

Fluorescence

Before the start of the experiment we clean blood pieces from the specimen and prepare a rectangular shape specimen. For each laser wavelength we perform 20 acquisitions.

Fluorescence

Spectra were analyzed with the principal component method. All spectra are well described by the sum of three components, presented in the picture below. As the components are alternating, spectra of real fluorophores are their linear combinations. By selection method we obtained spectra of narrow peaks.

Fluorescence

Peak 1 has maximum at 308 nm and it corresponds well with the fluorescence spectrum of tyrosine amino acid, peak 2 has maximum at 326 nm and is conditioned by amino acid tryptophan (depending on the surroundings fluorescence peak can occur in 320-360 nm diapason), peak 3 at 382 nm and matches the maximum in fluorescence spectrum of cross-links in collagen (but probably wider in the long-wave part, as collagen contains another fluorophore in an amount proportional to collagen).

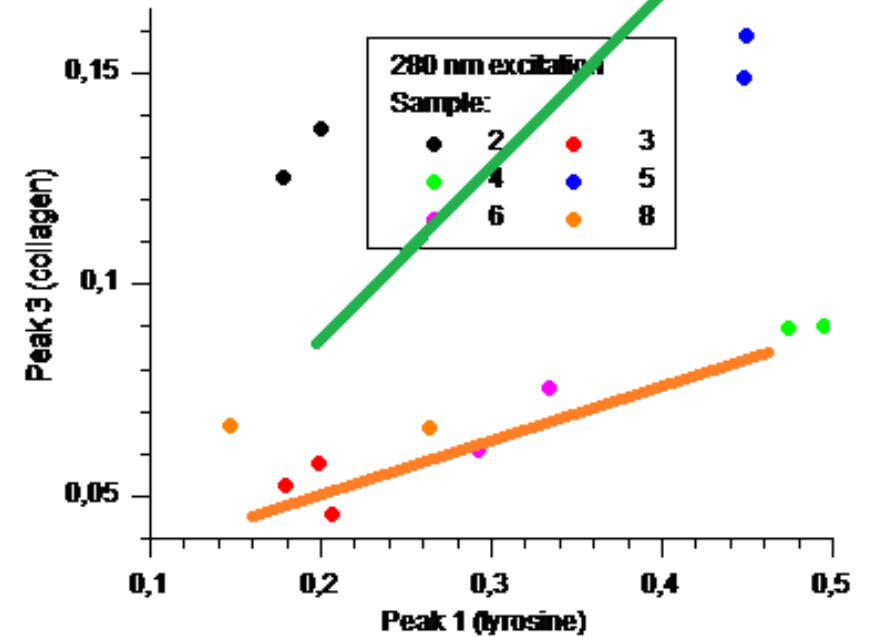

Fluorescence

— Ruptured aneurysms

— UnRuptured aneurysms

In here contributions to the spectrum of peaks 1 and 3 are shown normalized with the contribution of peak 2, for excitation wavelength 290 nm.

Maslov, **Application of laser-induced fluorescence method to the study of the cerebral aneurysm wall: First results and perspectives**, AIP Conference Proceedings **2125**, 020007 (2019); <https://doi.org/10.1063/1.5117367>

Part VI. Boundary conditions
problem: patient specific *vs* phantom,
rigid *vs* FSI, steady *vs* transient

The pathway

- The experimental research (mechanical test and investigation of protein consist).
- Numerical simulation of a blood flow with the aneurysm-dangerous behavior detecting.
- Statistical analysis of shapes.
- Mathematical modelling of the vessel wall.
- Mechanical-chemical model of the aneurysm growth and rupture.

Preoperative prediction model of the growth and rupture of a real aneurysm.

Tissue harvesting

Sample storage

Protein consist investigation

Mechanical test

Numerical calculation

Intraoperative velocity measurement

- A Doppler Transonic ultrasound sensor was used to measure the flow rate value distally to the aneurysm, both before and following treatment. The data was digitised using the open software WebPlotDigitizer (version 3.12) and the result obtained was used for the setup of the patient-specific FSI problem.
- Flow rate measurements: a-before treatment, b-following treatment and digitised waveform before treatment (on the right).

Mechanical test

Experiment on the rupture machine
Zwick/Roell Z100, Germany (LIH SB RAS)

- Experimental data (red line) and Mooney-Rivlin (blue line) approximation.

Numerical simulations in ANSYS. Setup

- Experimental setup:
- Unsteady flow
- Inlet condition: Time dependent velocity (flowrate) profile
- Outlet condition: Pressure
- Boundary surface condition (vessel wall): no slip condition (rigid walls)
- Finite volume method for Navier-Stokes equations.
- Incompressible viscous Newtonian fluid.

Conditions x Scenarios	Rigid walls	FSI scenarion A	FSI scenarion B	FSI scenarion C	FSI scenarion D
Inlet	flow rate	flow rate	flow rate	$V_0 + V_a \sin 2\pi t$	$V_0 + V_a \sin 2\pi t$
Outlet	Pressure	Pressure	Pressure	Pressure	Pressure
Surface type	Rigid	Elastic	Elastic	Elastic	Elastic
Surface condition	No slip	No slip +displacement	No slip +displacement	No slip +displacement	No slip +displacement
Blood vessel wall	-	Non-homogeneous	Homogeneous	Non-homogeneous	Homogeneous
Fluid - structure coupling	-	Pressure	Pressure	Pressure	Pressure

Results. streamlines

- Streamlines for Scenario A corresponding to different times, for rigid approach (on the left) and for FSI approach (on the right).

Results. High wss PATHWAY TO FIND RUPTURE SITE

There is a maximum difference in the value of WSS for the 2 previous approaches and this place exactly coincides with the place of rupture of the aneurysm.

Results

The diagrams of the minimums and maximums of the velocities and WSS or scenarios A-D and the rigid wall for each time moment T1-T4.

Results. Inflow concentration index

The IC index, which measures the degree of concentration of the flow stream entering the aneurysm, was also calculated:

$$ICI = \frac{Q_{in}/Q_v}{A_{in}/A_o}$$

Where Q_{in} is the flow rate into the aneurysm (inflow), Q_v is the flow rate in the parent artery, A_{in} is the area of the inflow region, and A_o is the area of the ostium surface.

Conclusions

- The calculations were performed in 4 scenarios with boundary conditions from both literature and patient-specific ones.
- The best localization of the rupture site is performed using the FSI approach and with the substitution of the velocity profile for a particular patient. In the case of a linear model of wall elasticity, the Young's modulus does not play a large role in localizing the rupture site.
- Verification of the aneurysm status was performed with using ICI- criterion. FSI – approach gave more plausible result of a such verification.

Part VII. Signs of cerebrovascular disease in terms of various components of the energy of the circulatory system

Chapter 1. Efficiency of vascular bypass: model study

Bypass surgery

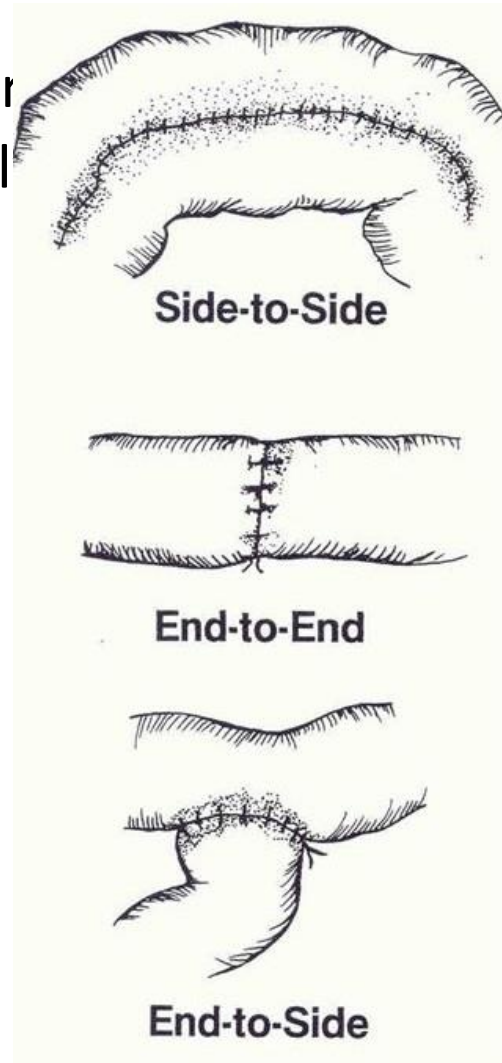

➤ Cerebral bypass is a junction of cerebral or cerebral-extracranial vessels to supply necessary volume of blood flow rate.

➤ **Applications:**

- Cerebral aneurysms
- Intracranial stenosis
- Tumors
- Moya-moya disease

➤ Types of main bypass techniques:

1. Side-to-side
2. End-to-end
3. End-to-side

The technique of Bypass surgery

The ZOO of THE PROBLEMS!!!

- The necessity of bypass surgery

TO BE OR NOT TO BE?

*That is the
question.*

W. Shakespeare

- Optimal placement of bypass graft

The ZOO of THE PROBLEMS!!!

- Optimal bypass angle and the Shape of an 'arteriometric window'

- ARTERIAL vs VIENUS graft

Optimal bypass angle

What is going on?

Viscous dissipation energy

We are about to analyze:

$$\mathbf{D} = 4\mu \int_{\Omega} |\omega|^2 d\Omega,$$

The energy which dissipate in the volume Ω . It's of sense to consider unit value, when you are going to compare different volumes.

Hemodynamic problem

- Steady blood flow for viscous inviscid fluid, Navier-Stokes equations:

- $$\begin{cases} \rho(u \nabla u - \mu \Delta u) = -\nabla p \\ \operatorname{div} u = 0 \end{cases}$$

- u – velocity
- ρ – density
- p – pressure

For the simulations we used unstructured tetrahedral mesh with 5 inflation layers.

Comparing of the mesh quality

flowrate difference (g/s)	M1-M2	M2-M3	M3-M4
LACA	0,0058	-0,0109	-0,0115
RACA	-0,0181	0,0071	0,0163
LPCoMA	0,0122	0,0053	0,0036

LMCA	-0,0163	-0,019	-0,015
RMCA	0,0257	0,0221	0,0093
ACoMA	-0,0089	-0,028	-0,0263

M1 – mesh with 1 million of elements

M2 – mesh with 2 million of elements

M3 – mesh with 3 million of elements

M4 – mesh with 4 million of elements

	M1	M2	M3	M4
Time of convergence (min)	12	16	21	30

What could we change?

Clinically we can change:

- graft diameter
- Blood flow rate (by choosing corresponding donor-artery)
- Angle of bypass graft installation

4 angles * 9 points for diameter ration * 9 points for the velocity ratio = 324 simulations

Value of Dissipative energy integral

Ratio of diameters

Ratio of the velocities

Optimal bypass placement angle analysis

Wall shear stress values (Max), Pa

$\pi/6$	$\pi/4$	$\pi/3$	$\pi/2$
0,828	0,421	0,468	0,527

V(cm/s),R(mm)	$\pi/6$	$\pi/4$	$\pi/3$	$\pi/2$
Minimal values of D integral, J/s * 10 ⁻⁷				
V ₁ =6, R ₁ =14	13523	17192	13365	13892
V ₁ =6 ,R ₁ =13.896	14799	16387	16246	15736
Maximal values of D integral, J/s * 10 ⁻⁷				
V ₁ =14 ,R ₁ =10,1	36734	48062	42211	39886

CONCLUSIONS

We demonstrated that $\pi/3$ angle is the best pathway of treatment in terms of bifurcation energy loss and $\pi/4$ is the worst one.

WSS doesn't play any role in this problem if we study on RIGID case. The investigation of FSI case is now in progress!

* Ruptured aneurysm

Main hydrodynamic characteristics

Computation and comparison of the essential hydrodynamic parameters (pressure, velocity, wall shear stress) did not reveal any parameter correlating with the aneurysm rupture.

Viscous dissipation energy

Total mechanical energy dissipating in a unit time interval:

$$W = 4\mu \int_{\Omega} |\omega|^2 d\Omega$$

μ – is the dynamic viscosity, $\omega = \nabla \times \mathbf{v}$ – is the vortex vector.

Additional quantities:

- Total dissipation energy per one period:

$$E = \int_0^T W dt$$

- Average dissipation energy per unit volume:

$$\bar{E} = E/V$$

- Dissipation energy rate per unit surface area:

$$W_s = W/S$$

- Total dissipation energy per unit surface area:

$$E_s = E/S$$

Results

- To assess a risk of the aneurysm rupture in case of multiple aneurysms, it is proposed to use viscous dissipation energy, which is the lowest for a ruptured aneurysm.

Energy of the system

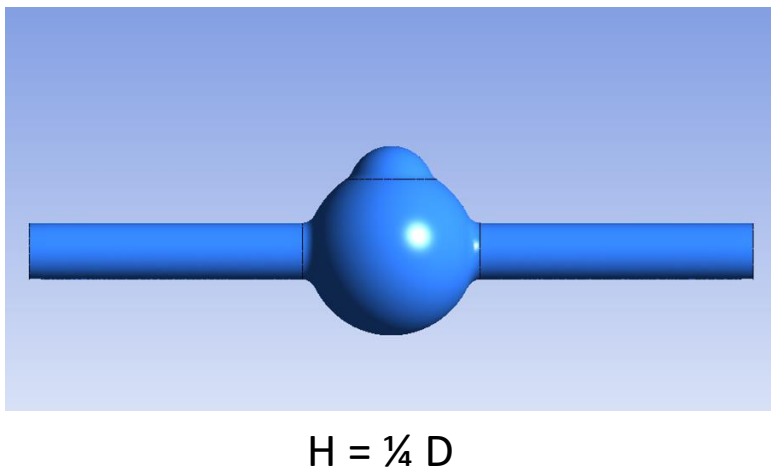

- Energy of the hydroelastic system: $E = E_e + E_k + E_b$
- Elastic energy: $E_e = \frac{Ed}{2(1-\nu^2)} \int_S dS$
- Kinetic energy: $E_k = \frac{1}{2} \int_V \rho |\mathbf{v}|^2 dV$
- Willmore bending energy: $E_b = \frac{E d^3}{24(1-\nu^2)} \int_S H^2 dS$
 - where E is Young's modulus, ν is Poisson's ratio, d is the wall thickness, H is the mean curvature
- Energy dissipated due to viscosity: $E_v = 4\mu \int_V |\boldsymbol{\omega}|^2 dV$

Aim

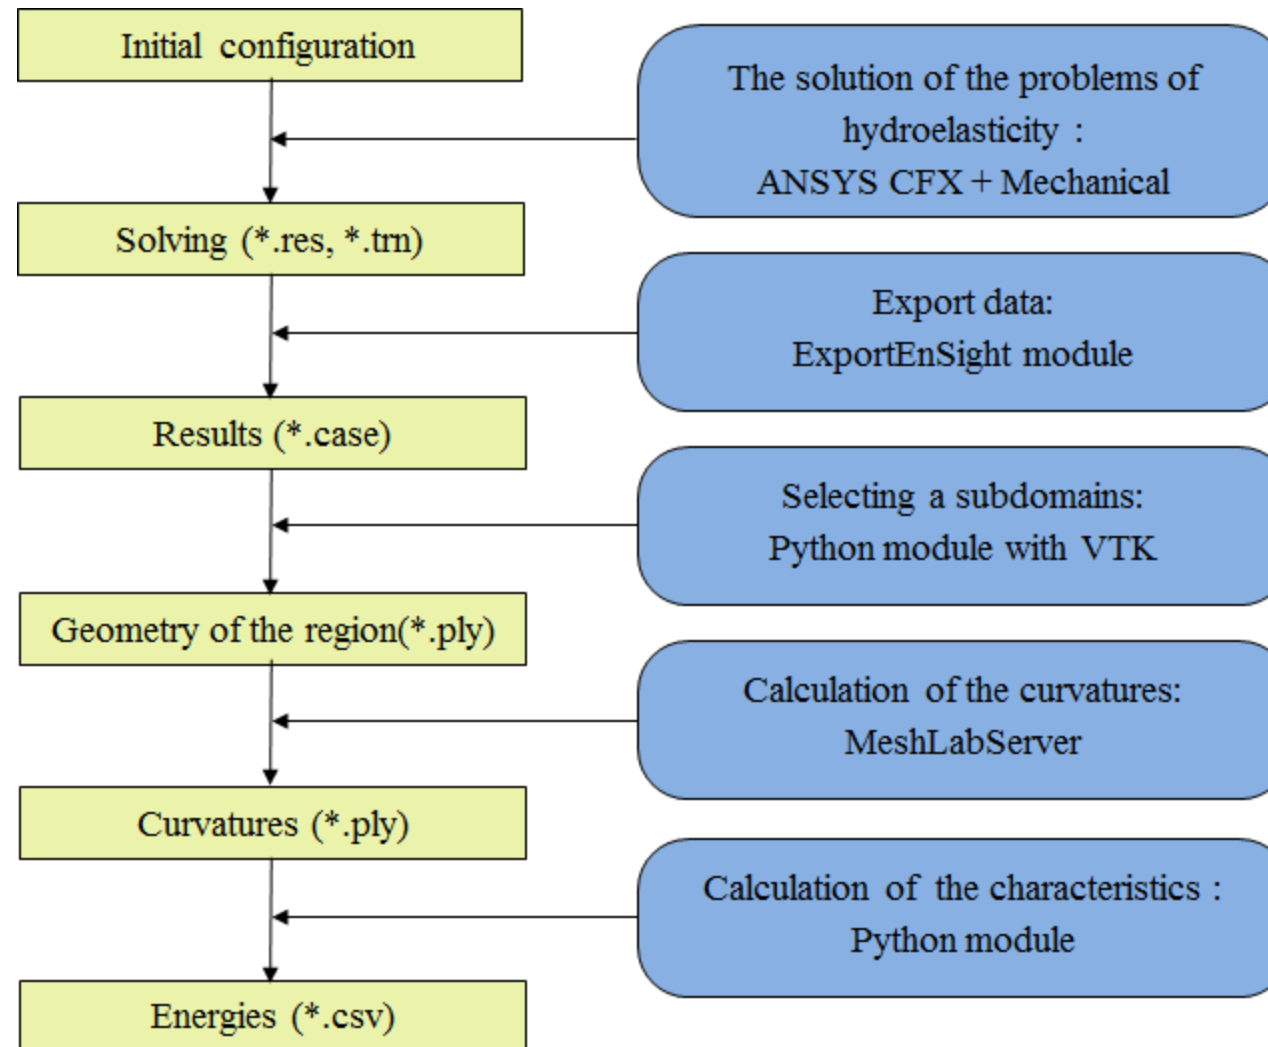

- The aim of this work is to assess different energy components in the hydroelastic system such as arterial aneurysms with diverticula.

Willmore functional

Decreases with angle

Simulation results: Kinetic energy

Simulation results: Viscous dissipation

Energy: 0°

E_e

$E_e + E_k$

$E_e + E_k + E_b$

E_v

$H = 0 D$

$H = \frac{1}{4} D$

$H = \frac{1}{2} D$

$H = \frac{3}{4} D$

Energy: 45°

E_e

$E_e + E_k$

$E_e + E_k + E_b$

E_v

$E_v + E_\Gamma$

$H = 0 D$

$H = \frac{1}{4} D$

$H = \frac{1}{2} D$

$H = \frac{3}{4} D$

The impact of energy components: Percentage from the total

Velocity–pressure diagrams

Velocity–pressure diagram for blood flow in cerebral aneurysm (**BEFORE** the treatment and **AFTER** the treatment)

Velocity–pressure diagrams: 45°

Inlet

Before
aneurysm

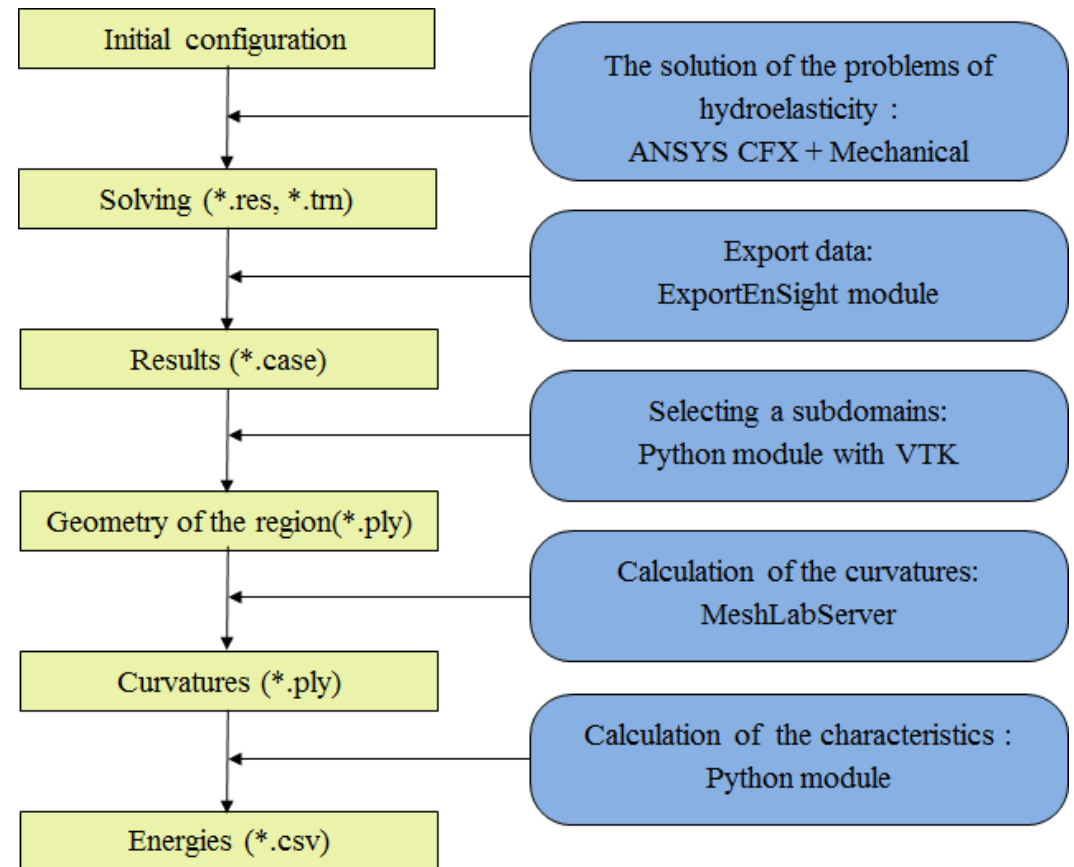

After
aneurysm

Outlet

Diverticulum

Conclusions

1. A computational framework for calculating the total energy of hydroelastic system is created.

Conclusions

2. Kinetic energy of the fluid is comparable with the bending energy of the interface

Conclusions

3. Calculation in 3D simulation FSI real diagrams “pressure-velocity” (p-v) for cerebral arterial aneurysm- BIRD-like diagram

Conclusions

4. Modification of (p-v) diagrams along vessel: nonlinear oscillation near AA, linear far from AA

Conclusions

5. Diverticulum in AA stabilizes fluid motion

45°
After
aneurysm

0 D

$\frac{1}{4}$ D

$\frac{1}{2}$ D

$\frac{3}{4}$ D

Conclusions

1. A computational framework for calculating the total energy of hydroelastic system is created.
2. Kinetic energy of the fluid is comparable with the bending energy of the interface
3. Calculation in 3D simulation FSI real diagrams “pressure-velocity” (p-v) for cerebral arterial aneurysm — bird-like diagram
4. Modification of (p-v) diagrams along vessel: nonlinear oscillation near AA, linear far from AA
5. Diverticulum in AA stabilizes fluid motion
